Software Engineer(Python Developer)

Summary

I have 7+ years of experience in developing Python projects as a software engineer. With my skills in front-end technologies such as modern JavaScript frameworks, I can work as a full-stack engineer. I have good experience and soft skills to lead teams and communicate with technical and non-technical people in a team. I can work closely with PMs to help manage projects/products since I have good knowledge of agile methodologies.

With that said any startup or established company could use my skills to benefit in building new things or maintaining great software.

I also shared my experiences in GitHub as open-source projects and wrote about my works in Medium. My articles have more than 100K views and my GitHub repositories get over 200 stars and forks regularly.

- Experienced with Python frameworks (Django, Flask)
- Good knowledge of JavaScript like jQuery and modern frameworks like React, Next.js
- Web Crawlers
- REST APIs
- Experienced with GIT and versioning
- Linux server management skills
- Experiences with automated testing tools like Selenium
- Experienced with MySQL, PostgreSQL, and MongoDB
- Experienced in working with high-load databases and database optimization
- Good knowledge of UI/UX concepts
- User behavior analytics and tracking UX tests
- Experienced with Scrum and Agile methodologies

Experience

YouTube importer for video sharing platform(todayscrypto.com)

TodaysCrypto.com is a video-sharing platform in the cryptocurrency niche. To encourage publishers to get on board this platform easily, we developed and maintain a YouTube importer for publishers that are coming from YouTube.

This script lets them import their whole videos including video files, tags, metadata, playlists, and entire data they had in their YouTube account.

2020

PriceBreaker, a Price monitor system

For "SaymanDigital" as an e-commerce platform for selling digital goods, It was important to know about its competitor's prices, so it can always set a competitive price or offer discounts to its customers. PriceBreaker was a solution to define a competitor's website and products so it can scrap the defined website and grab the price for each product.

I used Python Django to create an administration panel for registering competitor's websites and their products that needs to be monitored. Then using Python Requests and Beautiful Soup packages I scrap the website and grab the price. As I have our own price for each product I compare the prices and notify the admins when there is a lower price for a product.

Also, I created a parser to parse strings like ``className #ID .priceClass`` so the admin can define what should be scrapped in the structure of each website.

2020

"Intercultural communication" online course data analysis

For the "Intercultural Communication" online course of "The Intercultural Institute" in "Shanghai International Studies University" I scrapped comments and user relations(following status) and then I helped to create insights and analysis of the user's relation and comments.

For the scraping part, I used Python Selenium as the comments were fetched by the XHR requests. Also, Python comes in handy to analyze comments text and create topics based on the comments.

2019

Social media image generator for marketing

To scale up the amount of social media posts and speed up the process of creating social media posts for the marketing and content team, I created a Python Flask web interface so a member of the marketing team can choose one of the predefined templates and enters product title or any necessary text and hit a button to get the ready-to-share image for social media.

Besides Python flask, I used the PIL image library to make the uploaded images transparent and add images or text on the base template images.

2019	Sales and support process automation For an e-commerce platform which has more than 30K visits daily, it was necessary to facilitate and automate some of the sales and support processes. Two main aspects of this automation are registering imported goods in government panels for tax and customs and cross-checking customer's identities with banks to avoid fraud on payments. The major problem was that for these both aspects, there was no API. So in order to accomplish this automation, I used Python with Selenium to simulate what an operator does on the web panels. Also to check the result and status of the automated jobs, I created a web admin panel with Python Flask.
2018	Alak, Social media aggregator Utilizing Twitter API, I aggregate data for a certain hashtag or keyword. To achieve near-real-time data aggregating, I used multithread in Python.
2017	DIFTZ, An online B2B e-commerce platform Using Python Django framework we developed a B2B platform for product inquiries and a directory of companies that are active in importing/exporting goods. We managed to implement these functionalities: • Multi-language website and admin panel with Django localization • Products and company CRUD functionalities • Versioning and history of edits for product details • Products with dynamic attributes based on categories • Advanced permission and user access management
2015 - 2016	Python Module developments for Odoo ERP Odoo is a well known ERP system developed by Python and running on PostgreSQL. Back then I started my career as a Python developer by maintaining the Odoo ERP system for a private company. Going forward, I developed Python modules for the Odoo ERP system including: • Salary and payroll module • Extra HR features module • Extending CRM and reporting capabilities Maintaining and developing this ERP system for a company that stores it's data for years give me a good experience with both Python and Postgres. During upgrading this system, considering there was a major update from OpenERP to Odoo, I managed to transfer all data regardless of modules and data structures changes. I also managed to keep the newly developed modules or extended ones compatible with the latest version of the main ERP system.

Education

2010 - 2015	Information Technology Engineering B.S
